1. **Abstract**

National Metrology Institutes from 8 African countries, namely Egypt, Nigeria, Kenya, Tanzania, Zambia, Zimbabwe, Botswana, and South Africa have participated in an international supplementary comparison on the calibration of feeler gauges. This comparison was a part of larger supplementary comparison between 13 African countries for the calibration of hand measuring instruments. This larger comparison which was carried out during the period between December 2019 – December 2022 has been piloted by NIS, Egypt and has been registered in BIPM-KCDB database on December 2019 with the identifier AFRIMETS.L-S5. The artifacts have been prepared by NIS, Egypt and measured before sent to circulate between all participant countries in round-robin scheme and returned back again for NIS, Egypt where a final measurement was made for stability check. The main purpose of these comparisons is to support submission of CMCs for calibration of hand length measuring instruments in BIPM-KCDB.
1. **Introduction**

In December 2019, the Egyptian National Institute of Standards (NIS), Egypt has initiated a comparison for the calibration of length hand measuring instruments which is considered the standard activity in most African metrology institutes. It was not possible to conduct comparison for the calibration all length hand measuring instruments, so a number of 6 hand measuring instruments have been selected, which are external micrometer, caliper, dial gauge, setting rods, pin gauges and feeler gauges. The comparison was carried out during the period from December 2019 to December 2022 and was piloted by NIS, Egypt. The comparison has been registered in BIPM-KCDB database on December 2019 by the identifier AFRIMETS.L-S5 and was given the internal AFRIMET identifier AFRIMETS L11. The comparisons were carried out according to the protocol approved by all participants before initiating the comparison. The artifacts have been prepared and measured by NIS, Egypt before they were circulated between all participant countries in round-robin scheme and returned back again for NIS, Egypt where a final measurement was made for stability check. The main purpose of these comparisons is to support submission of CMCs for calibration of hand length measuring instruments in BIPM-KCDB.

In this report, 8 African countries, namely Egypt, Morocco, Nigeria, Tanzania, Zambia, Zimbabwe, Botswana, and South Africa have participated in an international supplementary comparison on the calibration of feeler gauges. It A feeler gauge of 13 blatts with thickness range from (0.05 – 1) mm was prepared by NIS, Egypt for the comparison.

Final report: Calibration of Feeler Gauges

2. **Participants**

8 African countries, namely Egypt, Morocco, Nigeria, Zambia, Zimbabwe, Botswana, and South Africa have participated in an international supplementary comparison on the calibration of feeler gauges. NIS, Egypt was acting as the pilot laboratory. The rest of the 13 countries which are Ghana, Ethiopia, Kenya, Malawi, and Mauritius did not participate in the feeler gauge comparison. The list of participants of this comparison are listed in the following table with their details:

3. **Form of Comparison**
The comparison is made according to round robin scheme. All artifacts including the feeler gauges are calibrated first at NIS, Egypt then shipped to the next country in the timetable, and so on. Malawi withdrew from the comparison since they were not ready by that time. Since not all countries participated in the 6 calibration activities, participants will differ from one report to the others. For feeler gauges, only 8 countries participated (shown in blue in figure 1).

![Figure 1: The transportation sequence and measurements of the artifacts.](image)

4. **Timetable**
The sequence of transferring the standards was made according to the protocol. However, delays occur due to the Covid-19 pandemic which took place at the start of the comparison in 2020. Table 2 shows the comparison planned timetable of the protocol. A delay of around one and half year almost from the planned time table.

## 5. Description of the artifact:

NIS artifact is feeler gauge as shown in figure 2 that has thickness range from (0.05 – 1) mm. 6 blatts of thickness values 0.2, 0.4, 0.6, 0.8 and 1.0 mm are considered for comparison measurements.
6. Calibration method used by each participant

Different methods are used by each participant for the calibration of feeler gauges. The used methods by each participant are summarized in table 3.

</tbody>
</table>

The status of some NMIs having traceability through NMISA standards did not affect the analysis of comparison results.

8. Traceability

Reference for the calibration of the feeler gauges should be traceable to SI unit of length though unbroken traceability chain. The following table demonstrates the traceability of the measurement of each participant that are deduced from the calibration report.

9. Analysis of the results

9.1. Transportation Stability

Drifts of the artifact’s values can occur during the transportation of the artifacts and handling over the long period of comparison. Therefore, a stability check must be performed to assure that this change will not affect the comparison results. The instability of the artifacts is assessed according to the following equation:

\[ \Delta_{ins} = |x_{NIS2} - x_{NIS1}| \]

where, \( x_{NIS2} \) is the measurement of the pilot (NIS, Egypt) after the comparison and \( x_{NIS1} \) is the measurement of the pilot before the comparison. The instability of each artifact during the transportation will add additional contribution to the uncertainty of the reference value.
AFRIMETS.L-S2.2.n01
Final report: Calibration of Feeler Gauges

\[ u_{ad}(x_i) = \frac{\Delta_{ins}}{2\sqrt{3}} \]

Additional criteria are applied to ensure the stability of the results which is:

\[ \Delta_{ins} \leq 0.9 \sqrt{u_{CRV}^2 + u_{min}^2} \]

where, the \( u_{CRV} \) is the uncertainty in the comparison reference value and \( u_{min} \) is the uncertainty of the participant with the lowest uncertainty.

Therefore, the total combined uncertainty for each participant after adding the uncertainty due to the stability will be

\[ u_a^2(x_i) = u^2(x_i) + u_{ad}^2(x_i) \]

### 9.2. Reference value of the comparison

The CRV (comparison reference value) was calculated using the weighted mean method according to the equation:
\[ x_{CRV} = \sum_{i=1}^{N} w_i x_i \]

Where \( w_i \) is the weights and is calculated by the equation:

\[ w_i = \frac{u_a^{-2}(x_i)}{\sum_{i=1}^{N} u_a^{-2}(x_i)} \]

and where \( u_a^2 \) is the uncertainty contribution of each participant including the uncertainty due to the stability analysis:

The standard uncertainty in the CRV value is calculated according to the following equation:

\[ u(x_{CRV}) = \sqrt{\frac{\sum_{i=1}^{N} u^2(x_i)}{\sum_{i=1}^{N} u_a^{-2}(x_i)}} \]

Calculation of the CRV and its uncertainty are given in table 6 and figure 2. The calculation is made after removing the inconsistent data according to section 9.3

Final report: Calibration of Feeler Gauges

Calibration of 0.2 mm feeler blatt

Calibration of 0.4 mm feeler blatt

Calibration of 0.6 mm feeler blatt
9.3. **Consistency check of the results**

Before calculating the CRV and its uncertainty a consistency of the comparison results must be examined. To determine the consistency of comparisons results Chi-square value $\chi^2_{obs}$ is calculated according to the following equation:

\[
\chi^2_{obs} = \sum_{i=1}^{n} \frac{(x_i - x_{CRV})^2}{u_i^2(x_i)}
\]
For the data to be consistent, the following condition must satisfy

\[ \Pr \{ \chi^2(v) > \chi^2_{\text{obs}} \} < 0.05 \]

Where \( v \) is the degrees of freedom which is the number of participant minus one and \( \Pr \) denotes “probability of” and \( \chi^2(v) \) is the inverse of the chi-square cumulative distribution function with degree of freedom specified by \( v \) for the probability of 0.05 (corresponding to the 95 \% level of confidence). In this case, the participant with the highest value of \( \chi^2_{\text{obs}} \) is excluded from the next round of evaluation and a new reference value, reference standard uncertainty, and chi-squared values are calculated again without the excluded laboratory. If the consistency check did not fail then \( y \) was accepted as the \( x_{\text{CRV}} \) and the \( u(x_{\text{CRV}}) \) are accepted. The number of participants \( N=8 \), therefore, the degrees of freedom \( v = N-1 = 7 \). From the Chi-Square table at 95 \% confidence level, we obtain \( \chi^2_{0.05} = 14.07 \).

<table>
<thead>
<tr>
<th>Nominal thickness, (mm)</th>

</tr>
</tbody>
</table>

9.3.1. Variation of solving inconsistency

For this comparison the consistency (\( \chi^2_{\text{obs}} \leq \chi^2_{0.05} \)) is failed for five measurements. The consistency for these measurements can be reached in different ways:

- By inserting an additional uncertainty \( s^2 \) following the Paul-Mandel method. This method allows reaching the consistency by enlarging relative uncertainties of all participants.

- By excluding the data of the participant with large deviations from tentative CRV.

At predraft A stage all participants approved the possibility of adding \( s^2 \) uncertainty and excluding data of any participant from the CRV calculations.
9.3.2. **Inserting an additional uncertainty following the Paul-Mandel method**

- The calculations with additional uncertainty $s^2$, which was added to relative uncertainties of each participant according to Paul-Mandel method, were made for feeler gauges of thickness values of 0.2, 0.4 and 0.6 mm. The $s^2$ value was found by trial and error method to satisfy the consistency conditions:

$$
\chi^2_{\text{obs}} \leq \chi^2_{0.05}(\nu)
$$

The chosen minimum additional uncertainty values $s^2$ and $\chi^2$ values for this case are presented in the table 10.

We can see that $s^2$ uncertainty including gives mostly small increase of total uncertainty and allows achieving results consistency.

<table>

9.4. Performance Evaluation

The purpose of the evaluation of performance methods is to provide a normalized performance evaluation so that all results are comparable and the performance of each participant can be measured. In such calibration schemes, the performance of the participants is evaluated by measuring whether the results of the participants are within the uncertainty of the CRV. The performance is evaluated using the normalized error number $E_n$, where:

$$E_n = \frac{(x_i - x_{CRV})}{\sqrt{U_{a_i}^2 + U_{CRV}^2}}$$

Where; $x_i$ and $U_{a_i}$ are the result and its corresponding adjusted expanded uncertainty of each participant, respectively. $x_{CRV}$ and $U_{CRV}$ are the CRV and its expanded uncertainty, respectively. $E_n$ is interpreted as follows:

$$|E_n| \leq 1 \rightarrow \text{Satisfactory performance}$$

$$|E_n| > 1 \rightarrow \text{Unsatisfactory performance}$$

10. Conclusion:
- The results from 8 National Metrology Institutes from Egypt, Morocco, Nigeria, Tanzania, Zambia, Zimbabwe, Botswana and South Africa have participated in an AFRIMET supplementary comparison on the calibration of Feeler gauges. The comparison reference value has obtained from the results using the weighted mean method after performing consistency check of the results using the Chai-square method. The Normalized error number $E_n$ is used to evaluate the performance of all participants. All results are found satisfactory except:
Final report: Calibration of Feeler Gauges

- LPEE/LNM @ 1.0 mm feeler gauge.
- TBS and ZMA @ 0.4 mm and 0.6 mm feeler gauges.
- BOBS @ 0.6 mm, 0.8 mm and 1.0 mm feeler gauges.
- NMISA @ 0.2 mm feeler gauge.
are found unsatisfactory (En>1).
