Abstract

Since 1983, five national metrology institutes have submitted six samples of known activity of $^{110}\text{Ag}^m$ to the International Reference System (SIR) for activity comparison at the Bureau International des Poids et Mesures. The activities ranged from about 1 MBq to 6 MBq. The degrees of equivalence between each equivalent activity measured in the SIR and the key comparison reference value (KCRV) have been calculated and the results are given in the form of a matrix. A graphical presentation is also shown. The results of this comparison have been approved by Section II of the Consultative Committee for Ionizing Radiation (CCRI(II)), comparison identifier BIPM.RI(II)-K1.Ag-110m.

1. Introduction

The SIR for activity measurements of $\gamma$-ray-emitting radionuclides was established in 1976. Each national metrology institute (NMI) may request a standard ampoule from the BIPM that is then filled (3.6 g) with the radionuclide in liquid (or gaseous) form. The NMI completes a submission form that details the standardization method used to determine the absolute activity of the radionuclide and the full uncertainty budget for the evaluation. The ampoules are sent to the BIPM where they are compared with standard sources of $^{226}\text{Ra}$ using pressurized ionization chambers. Details of the SIR method, experimental set-up and the determination of the equivalent activity are all given in [1].

Since its inception, the SIR has measured over 818 ampoules to give 590 independent results for 62 different radionuclides. The SIR makes it possible for national laboratories to check the reliability of their activity measurements at any time. This is achieved by the determination of the equivalent activity of the radionuclide and by comparison of the result with the key comparison reference value determined from the results of primary realizations. These comparisons are described as BIPM ongoing comparisons and the results form the basis of the BIPM key comparison database (KCDB) of the Mutual Recognition Arrangement (MRA) [2]. The comparison described in this report is known as the BIPM.RI(II)-K1.Ag-110m key comparison.
2. Participants

Five NMIs have submitted six ampoules for the comparison of $^{110}\text{Ag}^m$ activity measurements since 1983. The laboratory details are given in Table 1. In cases where the laboratory has changed its name since the original submission, both the earlier and the current acronyms are given, as it is the latter that are used in the KCDB.

3. NMI standardization methods

Each NMI that submits ampoules to the SIR has measured the activity either by a primary standardization method or by using a secondary method, for example a calibrated ionization chamber. In the latter case, the traceability of the calibration needs to be clearly identified to ensure that any correlations are taken into account.

A brief description of the standardization methods for each laboratory, the activities submitted and the relative standard uncertainties ($k = 1$) are given in Table 2. Details of the extrapolation method used by the IFIN are given in [3]. Full uncertainty budgets have been requested as part of the comparison protocol since 1998. When submitted by the NMIs, the uncertainty budgets are given in Appendix 1 attached to this report, as is the case for the OMH.

The half-life used by the BIPM is $249.8 (1) \text{ days}$ [4].

Details regarding the solution submitted are shown in Table 3, including any impurities, when present, as identified by the laboratories. When given, the standard uncertainties on the evaluations are shown. Recently the BIPM has developed a standard method for evaluating the activity of impurities using a calibrated Ge(Li) spectrometer [5]. The CCRI(II) agreed in 1999 [6] that this method should be followed according to the protocol described in [7] when an NMI makes such a request or when there appear to be discrepancies.

4. Results

All the submissions to the SIR since its inception in 1976 are maintained in a database known as the "mother-file". The activity measurements for $^{110}\text{Ag}$ arise from six ampoules and the SIR equivalent activity for each ampoule, $A_{ei}$, is given in Table 4 for each NMI, $i$. The dates of measurement in the SIR are given in Table 1. The relative standard uncertainties arising from the measurements in the SIR are also shown. This uncertainty is additional to that declared by the NMI for the activity measurement shown in Table 2. Although activities submitted are compared with a given source of $^{226}\text{Ra}$, all the SIR results are normalized to the radium source number 5 [1].

Following the advice of the CCRI(II), measurements were made at the BIPM concerning the impurity noted by the OMH. Although a slightly different impurity value was determined (within the expanded uncertainty), this does not produce a significant effect on the final result.

Measurements repeated at the BIPM after periods of up to one year later produced the same comparison results for the IFIN and for the OMH. These measurements confirm the validity of the half-life value used and the evaluation of the impurity corrections.

As no submissions were withdrawn and no recent submission has been identified as a pilot study, the results of each NMI are normally eligible for Appendix B of the MRA. However, the IFIN, at the time of publication of this report, is not designated in Appendix A of the MRA and consequently, until the laboratory is so designated, their results will not appear in Appendix B.

No international or regional comparison for this radionuclide has been held to date so no linking data are identified.

† the mean of the two $A_e$ values is used with an averaged uncertainty, as attributed to an individual entry [8]
4.1 The key comparison reference value

The key comparison reference value is derived from the unweighted mean of all the results submitted to the SIR with the following provisions:

a) only primary standardized solutions are accepted, or ionization chamber measurements that are directly traceable to a primary measurement in the laboratory;
b) each NMI has only one result (normally the most recent, and the mean if more than one ampoule is submitted);
c) any outliers are identified using a reduced chi-squared test and, if necessary, excluded from the KCRV using the normalized error test with a test value of four;
d) exclusions must be approved by the CCRI(II).

The reduced data set used for the evaluation of the KCRVs is known as the KCRV file and is the reduced data set from the SIR mother-file. Although the KCRV may be modified when other NMIs participate, on the advice of the Key Comparison Working Group of the CCRI(II), such modifications are only made by the CCRI(II), normally during one of its biennial meetings.

Consequently, the KCRV for $^{110}$Ag$^m$ has been identified as 5984 (8) kBq using the results from the NIST, NPL, OMH and the BNM-LNHB.

4.2 Degrees of equivalence

Every NMI that has submitted ampoules to the SIR is entitled to have one result included in Appendix B of the KCDB as long as the NMI is a signatory or designated institute listed in the MRA. Normally, the most recent result is the one included. Any NMI may withdraw its result only if all the participants agree.

The degree of equivalence of a given measurement standard is the degree to which this standard is consistent with the key comparison reference value [2]. The degree of equivalence is expressed quantitatively in terms of the deviation from the key comparison reference value and the expanded uncertainty of this deviation ($k = 2$). The degree of equivalence between any pair of national measurement standards is expressed in terms of their difference and the expanded uncertainty of this difference and is independent of the choice of key comparison reference value.

4.2.1 Comparison of a given NMI with the KCRV

The degree of equivalence of a particular NMI, $i$, with the key comparison reference value is expressed as the difference between the results

\[ D_i = A_{ei} - \text{KCRV} \]  \hspace{1cm} (1)

and the expanded uncertainty ($k = 2$) of this difference, $U_i$, known as the equivalence uncertainty, hence

\[ U_i = 2\mu_{Di} \]  \hspace{1cm} (2)

taking correlations into account as appropriate (see Appendix 2).
4.2.2 Comparison of any two NMIs with each other

The degree of equivalence, $D_{ij}$, between any pair of NMIs, $i$ and $j$, is expressed as the difference in their results

$$D_{ij} = D_i - D_j = A_{ei} - A_{ej}$$

(3)

and the expanded uncertainty of this difference $U_{ij}$ where

$$u_{D_{ij}}^2 = u_i^2 + u_j^2 - \sum_k \left( f_k u_{\text{corr},k}^i \right)^2 - \sum_k \left( f_k u_{\text{corr},k}^j \right)^2$$

(4)

and any obvious correlations in the standard uncertainties for a given component, $u_{\text{corr},k}$, between the NMIs (such as a traceable calibration) are subtracted using an appropriate correlation coefficient, $f_k$, as are normally those correlations coming from the SIR.

The uncertainties of the differences between the values assigned by individual NMIs and the key comparison reference value (KCRV) are not necessarily the same uncertainties that enter into the calculation of the uncertainties in the degrees of equivalence between a pair of participants. Consequently, the uncertainties in the table of degrees of equivalence cannot be generated from the column in the table that gives the uncertainty of each participant with respect to the KCRV. However, the effects of correlations have been treated in a simplified way as the degree of confidence in the uncertainties themselves does not warrant a more rigorous approach.

The uncertainties are not necessarily fully correlated and this is taken into account by applying an approximate factor, $f_k$, as indicated in Appendix 3 of this report.

Table 5 shows the matrix of all the degrees of equivalence as they will appear in Appendix B of the KCDB once all the laboratories are designated. It should be noted that for consistency within the KCDB, a simplified level of nomenclature is used with $A_{ei}$ replaced by $x_i$. The introductory text is that agreed for the comparison. The graph of the first column of results in Table 5, corresponding to the degrees of equivalence with respect to the KCRV (notated as $x_R$), is shown in Figure 1. This representation indicates in part the degree of equivalence between the NMIs but does not take into account the correlations between the different NMIs. However, the matrix of degrees of equivalence shown in yellow in Table 5 does take the correlations into account as appropriate.

Conclusion

The BIPM ongoing key comparison for $^{110}\text{Ag}^m$, BIPM.RI(II)-K1.Ag-110m currently comprises five results. These have been analysed with respect to the KCRV determined for this radionuclide, and with respect to each other. The matrix of degrees of equivalence has been approved by the CCRI(II) and is published in the BIPM key comparison database. Other results may be added as and when other NMIs contribute $^{110}\text{Ag}^m$ activity measurements to this comparison.
Acknowledgements

The authors would like to thank the NMIs for their participation in this comparison, Mr Christian Colas of the BIPM for his dedicated work in maintaining the SIR since its inception and for the thousands of measurements he has made over the years, and Dr Penelope Allisy-Roberts for her editorial assistance.

Table 5. Table of degrees of equivalence and introductory text for $^{110}\text{Ag}$m

Key comparison BIPM.RI(II)-K1.Ag-110m

**MEASURAND**: Equivalent activity of $^{110}\text{Ag}$m

Key comparison reference value: the SIR reference value for this radionuclide $x_R$ is 5.984 MBq, with a standard uncertainty $u_R$ of 0.008 MBq.

$x_R$ is computed from the mean of the participant results not including the IFIN result.

The degree of equivalence of each laboratory with respect to the reference value is given by a pair of terms:

$$D_i = (x_i - x_R)$$ and $$U_i$$, its expanded uncertainty ($k = 2$), both expressed in MBq, with $n$ the number of laboratories,

$$U_i = 2[(1 - 2/n)u_i^2 + (1/n^2)\sum u_j^2]^{1/2}$$ when each laboratory has contributed to the computation of $x_R$.

The degree of equivalence between two laboratories is given by a pair of terms:

$$D_{ij} = D_i - D_j = (x_i - x_j)$$ and $$U_{ij}$$, its expanded uncertainty ($k = 2$), both expressed in MBq.

The approximation $U_{ij} \sim 2(u_i^2 + u_j^2)^{1/2}$ is used in the following table.

Appendix 2. Evaluation of the uncertainty of the degree of equivalence

Table 5 indicates for each laboratory the degree of equivalence $D_i$ with its associated uncertainty $U_i$. This appendix presents the procedure used to evaluate these uncertainties.

The degree of equivalence of one laboratory is defined as the difference between the individual value of the equivalent activity $A_{ei}$ for an NMI $i$ and a suitable reference value which has been evaluated by the KCDB Working Group and the expanded uncertainty of this difference. Currently, the reference value, KCRV, for a given radionuclide is calculated as the arithmetic mean value of the SIR experimental entries for this radionuclide. Briefly at least four situations can occur depending on the consistency of the experimental SIR data sets:

1. All data are consistent and contribute to the reference value; this is the general case;

2. The value obtained by a laboratory that no longer exists, is used as long as it fits the usual quality criteria; it is taken into account when evaluating the reference value but does not appear in the matrices of results;

3. A value, that has been identified for example as an outlier, is not taken into account for the evaluation of the reference value but, nevertheless, the corresponding laboratory appears in the matrices of results.

The situation where a laboratory that no longer exists but contributes to the reference value and where an outlier has been identified in the data set can occur. This is a combination of both situation 2) and situation 3). The results, deduced from these two preceding cases, will also be presented here, case 4.

In the following the expression of the uncertainty for these three cases is considered on the assumption that the uncertainty of the different equivalent activities $A_{ei}$ are not correlated. For the sake of coherence with the definition of the variables used in the text, the following notation is used:

$$x_i = A_{ei} \quad \text{and} \quad u_i = u_{A_{ei}} \text{its uncertainty.}$$
Case 1. All \( n \) laboratories contribute to the reference value, and appear in Table 5. In this case obviously we have

\[
x_{\text{ref}} = \frac{\sum_{j=1}^{n} x_j}{n} \quad \text{(A – 1)}
\]

\[
D_i = x_i - x_{\text{ref}} \quad \text{(A – 2)}
\]

\[
D_i = x_i - \frac{\sum_{j=1}^{n} x_j}{n} = x_i \left(1 - \frac{1}{n}\right) - \frac{\sum_{j=1}^{n} x_j}{n} \quad \text{(A – 3)}
\]

At this stage the uncertainty of \( D_i \) has to be calculated. Applying the method of Gauß for the propagation of the uncertainties it is necessary to calculate the partial derivatives of \( D_i \) with respect to the \( x_i \).

So \[
\frac{\partial D_j}{\partial x_i} = \left(1 - \frac{1}{n}\right), \quad \text{and} \quad \text{(A – 4)}
\]

\[
\frac{\partial D_j}{\partial x_i} = -\frac{1}{n}, \quad \text{if} \quad j \neq i. \quad \text{(A – 5)}
\]

Then the total combined uncertainty becomes

\[
u_{c_i}^2 = \left(\frac{\partial D_i}{\partial x_i}\right)^2 u_i^2 + \sum_{j \neq i} \left(\frac{\partial D_i}{\partial x_j}\right)^2 u_j^2 \quad \text{(A – 6)}
\]

\[
eq \left(1 - \frac{1}{n}\right)^2 u_i^2 + \frac{1}{n^2} \sum_{j \neq i} u_j^2 \quad \text{(A – 7)}
\]

or, after recombination

\[
eq \left(1 - \frac{2}{n}\right) u_i^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2. \quad \text{(A – 8)}
\]

When a coverage factor of 2 is used (A-8) becomes

\[
U_i^2 = 2^2 \left[ \left(1 - \frac{2}{n}\right) u_i^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2 \right]. \quad \text{(A – 9)}
\]

Case 2. A laboratory was used to evaluate the reference value but does not appear in Table 5.

Let us assign the subscript \( n \) to the additional laboratory that contributes to the reference value. The uncertainty of this laboratory will appear only in the second part of equation (A-9). Accordingly, equation (A-9) becomes
$U_i^2 = 2^2 \left[ \left( 1 - \frac{2}{n} \right) u_i^2 + \frac{1}{n^2} \left( \sum_{j=1}^{n} u_j^2 \right) \right], \text{for } i = 1, n - 1. \tag{A-10}$

**Case 3.** The reference value was evaluated with all reported values except one.

For the sake of simplicity let us assign the subscript $n + 1$ to the ineligible laboratory so that the subscript for the other laboratories will run from 1 to $n$. Under this assumption the treatment of the ineligible laboratory will be slightly different and two formulae are deduced.

The ineligible laboratory does not contribute to the reference value, so the term $(1 - 2/n)$ in (A-9) reduces to 1 and the uncertainty is simply given by

$$U_{s+1}^2 = 2^2 \left[ u_{s+1}^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2 \right]. \tag{A-11}$$

In the evaluation of the uncertainty related to the $n$ other laboratories the contribution from laboratory $n + 1$ disappears totally and the uncertainty remains given by the expression (A-10) without restriction over the subscript range i.e.

$$U_i^2 = 2^2 \left[ \left( 1 - \frac{2}{n} \right) u_i^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2 \right], \text{for } i = 1, n - 1. \tag{A-12}$$

**Case 4.** A laboratory that no longer exists contributes to the reference value and an outlier has been identified for another laboratory.

Let us assign the subscript $n$ to the defunct existing laboratory so that the expression for the mean (A-1) remains applicable. In addition the outlier will be labelled by $n + 1$. For the $(n - 1)$ first laboratories which contribute to the mean value and appear in Table 5 the uncertainty of $D_i$ is given by

$$U_i^2 = 2^2 \left[ \left( 1 - \frac{2}{n} \right) u_i^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2 \right], \text{for } i = 1, n - 1. \tag{A-13}$$

For the laboratory $n + 1$ that is ineligible for the KCRV, its coefficient $(1 - 2/n)$ in (A-13) reduces to 1 and the expression of the uncertainty in Table 5 becomes

$$U_{s+1}^2 = 2^2 \left[ u_{s+1}^2 + \frac{1}{n^2} \sum_{j=1}^{n} u_j^2 \right], \tag{A-14}$$

similar to (A-11).
Appendix 3. Details of the correlation coefficients used in the evaluation of uncertainties in Table 5.

As only one NMI has submitted a full uncertainty budget, the only correlations that can be considered between pairs of NMIs are those arising from the use of the SIR.

As the half-life is relatively long, the uncertainty in this value is an insignificant component so can be neglected in the correlations.

The relative uncertainty due to the Ra source used can be taken as completely correlated when the same source is used and thus $f_k = 1$ in (4); in other cases this value has been taken as 0.3.
